

threshold vs the S4.4 amplitude bracket

Bracket (shaded / dashed upper / dash-dot lower-slab) is a fractional polarized amplitude referred to T_{sky} , not T_{sys} (T_{sys}/T_{sky} within 1.7% of 1, loading only -- no amplifier noise in this chain -- and not rescaled here).

The dashed UPPER line alone derives from θ_c , which is clamped to the search grid at every band shown: it is a clamp-derived upper bound, overstated by ~ 3 decades, and is not computable from this map.

The dash-dot lower-slab and shaded lower-dispersion ends contain no θ_c and stand.
